i got this error

public/mp2-0: FAIL (0/3) (0.6s)

Invalid first print data: [idx 0] { addr: 0x0000000087f4e018, as_ptr: 0x0000000900000003, as_obj: { tp: 3, ref: 9, readable: 1, writable: 1, pipe: 0x0000000000000000, ip: 0x0000000080035448, off: 0, major: 1 } }

QEMU output saved to out/public/mp2-0.out.failed

I'm confused about what the tests expect for the `print_kmem_cache()` function. The spec says to print objects 'in the order defined by slab::freelist' and mentions full/free slabs are optional, but my implementation fails with 'Invalid first print data' errors. Should I print objects in freelist order or index order? And should I include only partial slabs or all slab types (partial, full, free) in the output?"

Appreciate any help or clarification!

Saturday

Hello there. I understand your confusion — I had the same question at first.
Let me share my understanding of the spec, and feel free to correct me if you spot anything.

From what I see, the spec wants you to:
1. Only print objects from partial slabs. There's no need to print full or free slabs. (mentioned in the spec)
2. Print the objects in memory order, not in the order you traverse the freelist.

You can also notice this if you observe the outputs shared by others in other discussions, and you would

realize that the grader expects the objects to appear in memory order, not freelist order.

Hope this helps — good luck!
